## HomeWork-4, Algorithms and Problem Solving

Note :- I have referred textbook, lecture notes and so many random websites like chegg & stack overflow and also worked with few of my classmates.

### Problem 1: Problem 6.10 from DPV

Let  $P[i][j]$  be the probability of obtaining  $j$  heads in  $i$  coins

Basecase for recursion formulation is  $P[0][0] = 1$   
(probability of getting 0 heads in 0 coins)

Recursion can be given as  $P[i][j] = P[i-1][j](1-P[i]) + P[i-1][j-1]P[i]$

where probabilities of  $n$  coins be in  $P[1, 2, \dots, n]$

This represents the probabilities of both getting head in  $i$ th coin and reducing the  $j$  and not obtaining head & not reducing the  $j$

Algorithm:

let  $P$  be a  $n \times (k+1)$  array of zeros

$P[0][0] = 1$

for  $i$  from 1 to  $n$ :

$P[i][0] = P[i-1][0](1-P[i])$

for  $j$  from 1 to  $\min(i, k)$ :

$P[i][j] = P[i-1][j](1-P[i]) + P[i-1][j-1]P[i]$

return  $P[n][k]$

And the time complexity for the above algorithm is  $O(n^2)$  //

### Problem 2: Problem 6.6 from DPV

This can be solved by DP. Let  $dp[i][j]$  be true if it is possible to parathesise the substring from index  $i$  to index  $j$  (inclusive) in such a way that the value of the resulting expression is "a".

Base Case by recursion:  $dp[i][j] = 1$  if it's a at i else 0

Recursion:  $dp[i][j]$  depends on the values of  $dp[i][j-1]$ ,  $dp[i+1][j]$  and  $dp[i+1][j-1]$

The values of  $dp$  for substrings of length 2 and higher are then filled in by the function using a nested loop. It considers all possible ways to divide each substring of length  $k$  into two non-empty substrings for each substring in order to find a way to parenthesize the two substrings so that their product evaluates to "a", and then it uses the multiplication table to combine the two products to create a product that evaluates to "a" for the entire substring. If a solution is discovered, the function sets  $dp[i][i+k-1]$  to 1, indicating that the substring can be parenthesized in order for it to evaluate to "a". Time complexity will be  $O(n^3)$

Algorithm:

function can\_parenthesize(s)

$n = \text{length}(s)$

$dp = \text{array of size } n \times n, \text{ initialized to } 0$

for  $i$  from 0 to  $n-1$  do:

if  $s[i] == "a"$  then

$dp[i][i] = 1$

for  $k$  from 2 to  $n$  do

for  $i$  from 0 to  $n-k$  do

$j = i + k - 1$

for  $p$  from  $i$  to  $j-1$  do

if  $dp[i][p] == 1$  and  $dp[p+1][j] == 1$  and  $M[s[p], s[j]] == "a"$  then

$dp[i][j] = 1$

return  $dp[0][n-1]$

Here  $M$  is the multiplication table given in the question

Problem 3 : problem 6.12 from DPV.

Let us assume a DP array  $dp[n][n]$  where  $n$  is the number of vertices in the polygon.

We assume the subproblem as  $A(i, j)$  where  $i, j$  represent the vertex numbers in the given polygon and finds out the cost of triangulation in the sub polygon formed by those vertices.

BaseCase :  $dp[i][i+1] = 0$  for all  $i$ .

Recursion case :  $dp[i][j] = \min(dp[i][k], \text{distance}(P[i], P[j]) + dp[k][j] + dp[i][k])$

where distance gives the distance between the vertices and  $k$  ranges from  $i+1$  to  $j-1$ . So this gives the distance based on the cost of the previously calculated vertices and the newly calculated cost.

Algorithm:

$n = \text{length}(P)$

$dp = \text{array of size } n \times n, \text{ initialized to infinity}$

BaseCase : for  $i$  from 1 to  $n-2$  do

$dp[i][i+1] = 0$

Algorithm

for  $i$  from 1 to  $n-2$  do

$dp[i][i+1] = 0$

for len from 3 to  $n$ :

for  $i$  from 1 to  $n - \text{len} + 1$ :

$j = i + \text{len} - 1$

for  $k$  from  $i+1$  to  $j-1$ :

$\text{cost} = \text{distance}(P[i], P[j]) + dp[i][k] + dp[k][j]$

$dp[i][j] = \min(dp[i][j], \text{cost})$

return  $dp[1][n]$

Problem 4: Problem 6.17 from DPV.

Let us assume a DP array  $A[v][n]$  where  $v$  is the change requested and  $n$  is the denomination of the coins i.e.  $x_1, x_2, \dots, x_n$

Base Case:  $A[0][j] = \text{true}$  because we can make 0 change with any coins given

Recursion:

$$A[i][j] = A[i][j-1] \text{ or } A[i-x_j][j] \quad (\text{if } i \geq x_j)$$

$$A[i][j] = A[i][j-1] \quad (\text{if } i < x_j)$$

Algorithm

Function make-change( $x[1..n], v$ ):

$A = \text{new boolean}[v+1][n+1]$

for  $j=0$  to  $n$ :

$A[0][j] = \text{true}$

for  $i=1$  to  $v$ :

for  $j=1$  to  $n$ :

$A[i][j] = A[i][j-1]$

if  $i \geq x[j]$ :

$A[i][j] = A[i][j] \text{ or } A[i-x[j]][j]$

return  $A[v][n]$

After base case, if we can generate the change with  $i$  coins then we can do the same change with  $i+1$  coins [induction theory]. Else we take other possibilities by considering change for  $i-x[j]$  coins

Time complexity is  $O(n^2)$
